October, 2021

Using Azure Machine Learning SDK to run heavy scripts on the cloud

Daniel Labbe

Daniel Labbe

Sr. Customer Engineer, Data & AI domain @ Microsoft

Master Student @ The University of Edinburgh

Teacher Assistant @ Udemy

Data Scientist

- 23+ years of experience in data related roles
- Azure Data Scientist Associate, Azure AI Engineer Associate
- 8+ years dealing with Data Science
- 15,000+ questions answered in courses (400,000+ students)
- Presented workshops in Data Science, Python, ML & AI
- Engaged in StackOverflow and Kaggle

Session Objectives

Discuss the **elasticity** of cloud solutions

Discuss the **flexibility** of Azure Machine Learning

Discuss the **convenience** of local SDKs

Motivations

Heavy workloads might not be suited for your local Infrastructure

- **Time consuming**
- Tech dependent – new tech **demands new hardware**
- Demands **upfront investments**
- **Limits the capacity** of experimentation

Azure Machine Learning workspace is virtually **free***

- Adjacent resources have costs
- Storage Account, Key Vault, Apps Insights have **marginal costs**
- Computes can be expensive, but **pay as you go**

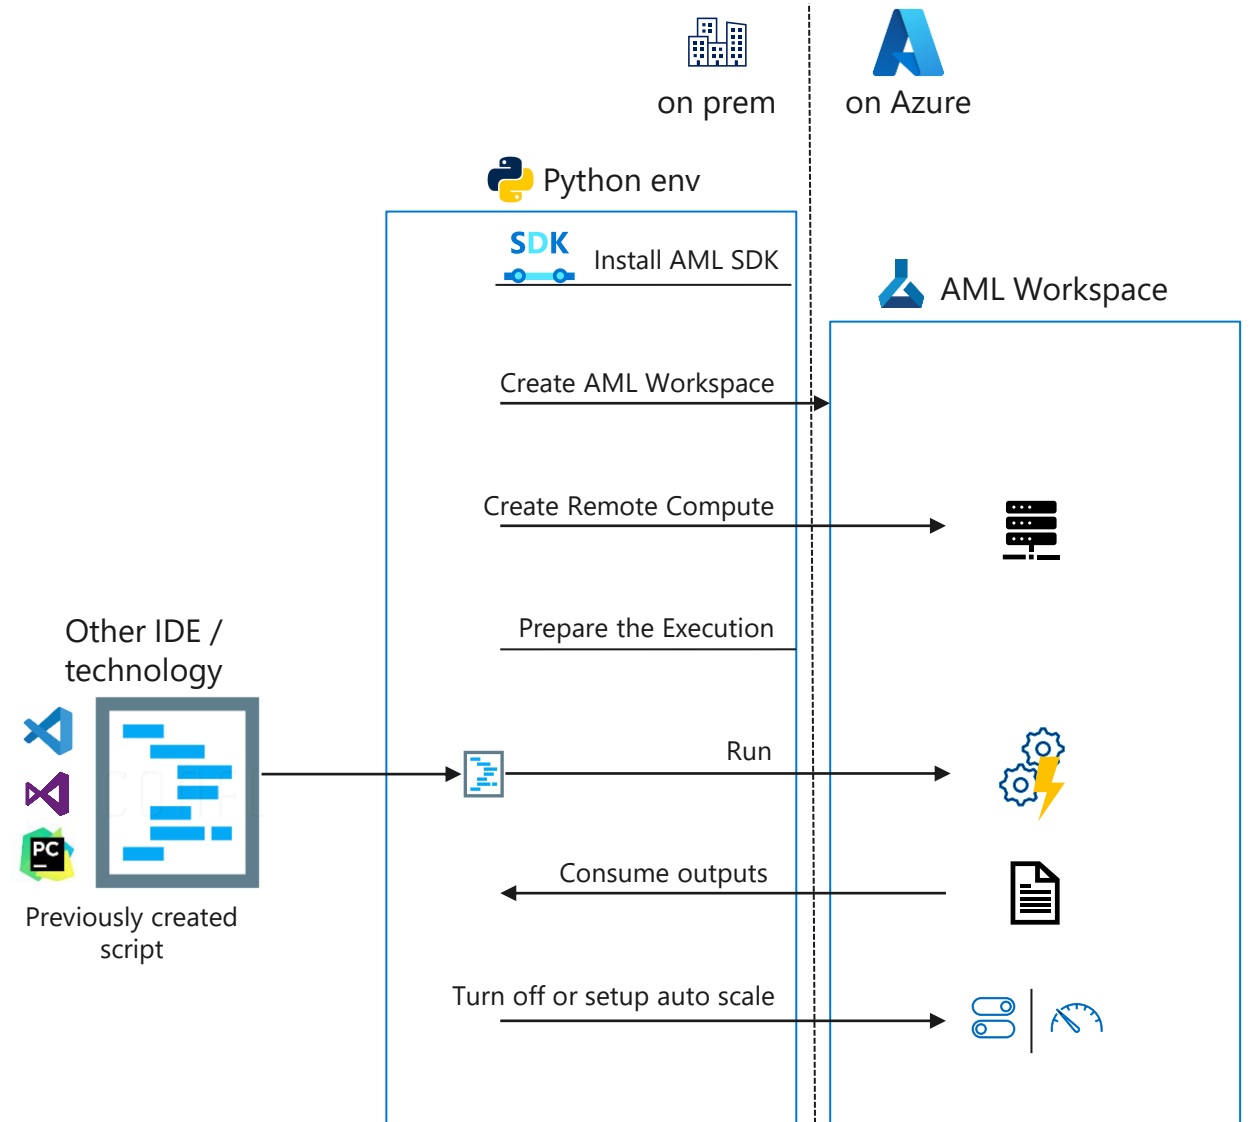

Azure Machine Learning can handle **more than ML Workloads**

- AML is **flexible** to different maturity level
- AML can handle well **hybrid architectures** for on-prem/on-cloud environments
- AML can run scripts, **not only training scripts**

Solution Overview

- Provision cloud resources using code (infra-as-code)
- Run previously created scripts on remote computes
- Turn off or auto scale the compute resources

Monte Carlo Simulations

Monte Carlo simulations are used to model the probability of different outcomes in a process that cannot easily be predicted due to the intervention of random variables. It is a technique used to understand the impact of risk and uncertainty in prediction and forecasting models.

Monte Carlo Simulations

Pythonic implementation

Meaning that inside the "previously created script" to run, there will be no parallelization in the demo

Sales Rep Commission

The demo considered a simplistic use case of the Monte Carlo simulations focusing on the execution, not on the implementation

Statistical Output Interpretation

In this example, the uncertainty experimented is the number of sales to compute commissions, expecting a normally distributed outcome with the range of ± 2 std covering 95% of the possibilities

Demo

Using a local Jupyter instance to
start a set of Monte Carlo
simulations on Azure via AML SDK

Benchmark

Scaling from 10^1 to 10^6 simulations in different compute sizes and prices for a parallelized implementation in R

Compute Sizes and Prices

E series for **memory** optimized
F series for **compute** optimized
D series for **general purpose** workload
N series for **GPU** optimized

Tim ings

Cost per Execution

A close-up, slightly blurred photograph of a typewriter keyboard. The keys are dark and arranged in rows. A white, semi-transparent rectangular box is centered over the keyboard, containing the word "Questions?" in a white, serif font. The lighting is soft, highlighting the texture of the keys and the metallic parts of the typewriter mechanism.

Questions?
